1. Abstract

This paper estimates an optimal production levels for the different products manufactured at ICI, a multinational company in Pakistan. The revised simplex method is used to maximize the profit generated in 2010 subjected to cost resource constraints. The production of Polyester, Soda Ash, Paints and Chemicals are taken into consideration. The production of the Soda Ash is most productive contributing more to the objective function. In the year 2010, the company was earning R.s 3, 273,756,000 from the production of these products. This amount raises by R.s 189,708, R.s 989,238, R.s 15,594,377 and R.s 45,408,040 by changing production patterns within the first, second, third and fourth digits respectively. The company can earn significant profit by operating on the proposed production forecasts. The top management and decision makers can maximize the profit of the company within the name plate production capacity, setting up the future goals and outlook of the company.

KEYWORDS: Production Planning, Linear Programming, Sensitivity, Simplex Method, Supply Chain, Management Science.

2. Introduction

Linear programming is a powerful tool for the optimal allocation of scares resources with the objective of maximization of profit. Simplex method first devised by Dantzig in 1947 is used to solve LP's. He then extended the method for planning/scheduling dynamically. As such the development of a mathematical model is necessary in order to make best choice among several alternatives using its numerical values (Dantzig, 1963), (Adams, 1969), (Hiller et al., 1995). The noble laureate Leonid Kantorovich (USSR) and Tjalling Koopmas (USA) were awarded for their work on the optimal allocation of resources using the technique of linear programming. Bierman and Bonini (1973) pointed its usefulness in decision making process of making the best choice with several different alternatives. Linear programming is about making rules and relations with limited funds and technological restrictions (Andrade, 1990). David (1982) and Nearing and Tucker (1993) emphasized the application of the tool in tactical and strategic management. The simplex method is regarded as the most important and credible method devised of the mid 20^{th} century. Now a day it is a benchmark optimizing tool saving thousands and millions of dollars in many organizations. Linear programming can be effectively applied to diverse fields including transportation, telecommunication, energy, blending and production, airline crew scheduling, network flows (Winston and Albright, 2000), (Anderson et al., 2002).

Linear programming has been used in operational management such as aggregate production planning, service productivity, product planning, product routing, process control, inventory control and distribution scheduling, plant location and material handling (Manley and Threadgill, 1991), (Zappe *et al.*, 1993), (Jacob *et al.*, 1996). Linear programming works for maximizing the company's profits with the minimal consumption of resources (Chopra and Meindl, 2001), (Thomas, 2002), (Stadtler, 2000), (Taghrid and Hassan, 2009), (Fagoyinbo *et al.*, 2011). This research takes into consideration the sale/production of the four main products of ICI Pakistan Limited. The profit and loss data has been obtained from the keenly prepared annual book of the year 2010. The study points out the product that is contributing more to the objective function (profit). The simplex method is used to get the best possible consumption of the resources (cost) of the problem for ICI Pakistan. As a matter of nature some bottleneck may occur, e.g. the demand for one product may be greater than other. This research considers such bottlenecks in the formulation and modeling of the linear programming problem.

3. MATERIALS AND METHODS

A linear programming problem with "n" decision variables and "m" constraints can be mathematically modeled as (Taha, 1975), (Zeleny, 1982), (Winston, 1995), (Higle and Wallence, 2003).

Maximize.
$$z = c_1 x_1 + c_2 x_2 + \dots + c_n x_n$$

s.t

 $a_{11}x_1 + a_{12}x_2 + \ldots + a_{1n}x_n \le b_1$

 $a_{21}x_1 + a_{22}x_2 + \ldots + a_{2n}x_n \le b_2$

•

```
.a_{n1}x_1 + a_{22}x_2 + \ldots + a_{mn}x_n \le b_m
```

 $x_{1,}x_{2},\ldots x_{n} \geq 0$

This can be written as,

 $\max z = c^t x$

s.t,

 $Ax \leq b$,

 $x \ge 0$

ICI Pakistan is a limited company enlisted in Karachi, Lahore and Islamabad Stock Exchange. The company is engaged in manufacturing of Polyester, Soda Ash, Paints and Chemicals. The profit and loss data of the manufactured products of the company is obtained from the annual book of the year 2010. In this regard, the commission and discounts paid by the company are presented in Table 1.

Table 1 Tax, Commission, Duty, Discounts to Distributors and Customers.

Table 2 contains the cost of goods sold of the four mentioned products. The selling and distribution expenses and the administration and general expenses incurred on the products in 2010 are presented in Table 2 and Table 3 respectively.

Table 2 Cost of Goods Sold.

Table 3 Selling and Distribution Expenses.

Table 4 Administration and General Expenses.

The per metric tons/per kilo liters profit and expenses of the company are summarized in the Table 5.

Table 5 Summarized Profit and Loss of the Company.

Let x1, x2, x3, and x4 represent the quantity sold/produced of the Polyester, Soda Ash, Paints and Chemicals respectively, then the initial linear programming model can be formulated as,

Maximize z=15586.93x1+3066.59x2+3885.23x3+14404.69x4

408.02x1+967.14x2+28533.76x3+9711.33x4<=1472112000

120411.1x1 + 17385.47x2 + 96443.35x3 + 138703.3x4 <= 26179724000

559.18x1+696.13x2+22133.74x3+9085.12x4 <= 11816830002044.18x1+996.05x2+12985.97x3+9413.92x4 <= 1150763000 x1>= 129730 x2>= 291860 x3>= 34566 x4>= 15508 The next section discusses the solution of the initial model using the Excel Solver.

4. RESULTS AND DISCUSSIONS

The solution of the initially proposed model is obtained by utilizing the Microsoft Excel® solver. The solution of the model is presented in Figure 1.

Figure 1 Answer Report.

Figure 2 Limits Report.

The answer report of the initial linear programming model shows that the company can generate a profit of R.s 3273786300, an amount R.s 30,300 greater than the presently operating profit. The cost of goods sold, quantity sold of polyester, paints and chemicals are binding constraints and they are consumed fully whereas all the other constraints are non binding and are available for the future production runs. The limits report in Figure 2 shows the lower and upper limits of the variables in which the solution is optimal.

4.1 Sensitivity Analysis and Different Production Runs

The sensitivity analysis of the model gives important information about the manufacturing process (Kinc, 2008).The sensitivity report of the model is given in the Figure 3.

Figure 3 Sensitivity Report.

The reduced cost shows that quantity produced of the soda ash and then that of polyester takes less amount of cost in the production run whereas that of quantity of paints and chemicals consume much of the cost. The shadow price shows that an R.s 1 spent as the cost of goods sold is contributing at the rate of R.s 0.176 to the maximization of the profit for future production runs based on the initial linear programming model. Several production runs of the optimized model on various production spaces within the nameplate production capacity are summarized in the Table 6.

Table 6 Various Production Runs in The Name Plate Capacity.

5. CONCLUSIONS AND RECOMMENDATIONS

The techniques of linear programming and sensitivity analysis were used to maximize the profit generated from the production patterns of the ICI Pakistan. Four different products manufactured at the company were taken into consideration. The analysis predicted that the production of Soda Ash is contributing more than other products to the objective function. The company is already a prime supplier of the Soda Ash in the region. The sensitivity analysis reveals the fact that a cost of R.s 1 spent as the cost the goods sold returns at the rate of R.s 0.176. The company can save profits of R.s 189,708, R.s 989,238, R.s 15,594,377 and R.s 45,408,040 by changing its production space within the first, second, third and fourth digits respectively. The research reveals that among the other products Soda Ash is more profitable to the company and the company should give more attention to its production to maximize its profit. The research is significant in the sense that it will assist the top management of the company in making corrective decisions well in time using the methods of linear programming. This will determine the future production patterns and outlook resulting in the establishment of new production units, while planning for maximizing profits of the company.
